First: where is the freedom to update one's name?

Second: The EO "Defending Women" is itself scientifically inaccurate. Humans have 6 karyotypes, not just 2 (X, XX, XXX+, XXY, XYY, XY).

Third, genetic karyotyping is not (and should not be) standard newborn practice.

Fourth: Human chimeras exist. Their cells are not identical throughout the body. Many humans are a mosaic of at least two different sets of chromosomes.

Fifth, natural mutations affect the body's response to hormones during gestation, puberty, and childhood. Reference the Guevadoces of the Dominican Republic who have a specific form of androgen insensitivity.

Sixth, natural hormone levels also affect one's secondary sex characteristics. That's how bearded women happen: their own bodies make too much testosterone.
