Comments on Draft Integrated Science Assessment for Lead

Our comments are focused on the section of Appendix 3 to the Draft Integrated Science Assessment for Lead (ISA) which discusses the studies which support the current association of blood lead with IQ. In particular, we are concerned that the EPA has not considered Van Landingham et al. 2020 which points out concerns about the effects of confounders on the modeling of the Lanphear cohort data. In addition, we think there could be more clarity and consistency in the information supplied on the “supporting” studies since 2013 and that the heterogeneity seen in the results from these studies adds uncertainty to the analyses done. Specific items EPA should consider are outlined below.

June 8, 2023

1. Section 3.5.1.6.1, Concentration-Response Function, refers to both Lanphear et al. 2005, 2019 and Crump et al. 2013, but fails to mention Van Landingham et al. 2020 which analyzed the same data as Lanphear and Crump but including confounding variables (variables with interaction with the BPb variable). Van Landingham et al. 2020 raises concerns about the modeling in the low exposure range. Their analysis shows that “confounders influence IQ estimates in a quantifiable way that may exceed or at least obscure previously reported effects of blood lead on IQ with blood lead levels below 5 µg/dL; however, limitations in the datasets make predictions of the low dose dose/response analysis questionable”. The Van Landingham et al. 2020 analysis should be mentioned in this section. Email correspondence with EPA epidemiologists regarding the Van Landingham et al. 2020 publication, and associated correspondence with the Journal *Critical Reviews in Toxicology* regarding the submission of an erratum for the publication are included as attachments to these comments.
2. Consistent descriptions from the EPA of the studies considered would help in interpreting the results from the modeling of these studies. Instead of “imprecise associations” or “less precise,” it would be more accurate to report these associations as either statistically significant or not statistically significant.
3. Section 3.5.7.3.3 is entitled ‘Confounding’ but seems to be discussing covariates. We could find no definition of confounding in the ISA document. From the way the terms confounders and covariates are used in the document, there seems to be confusion about the difference between a variable used in modeling that is a covariate and one that is a confounder. We recommend that the document should have a definition of these terms, and to make sure that the the appropriate term is applied when describing the studies reported in this section. Unfortunately, some of the authors of these publications do not seem to know the difference in these terms either,

F +1 206 336 1651
<https://ramboll.com>

and due to this fact and poor model reporting in some publications, there is additional uncertainty in the results reported. Three publications that discuss the differences between covariates and confounders are Field-Fote 2019, Gurka 2018, and Van Landingham et al. 2020.

4. Section 3.5.1.1, Full-Scale IQ in Children, states that: “(s)everal recent longitudinal studies add to the evidence informing the relationship between BLL and IQ in children. Heterogeneity in the magnitude and direction of the associations, which was potentially explained by race/ethnicity, sex, and modeling choices such as adjustment for other metals or chemicals was present. This heterogeneity did not weaken the larger body of supporting evidence. Overall, recent studies generally corroborated previous epidemiologic observations of associations between Pb exposure and IQ in children with relatively low blood Pb concentrations (≤ 5 $\mu\text{g/dL}$) (see Figure 3-4 and Evidence Inventory Table 3-2E).” We are concerned that there was insufficient attention paid to this heterogeneity and to the use or lack of meaningful covariates and confounders in the modeling performed in these studies.

In the 11 distinct studies published since 2003 (as indicated in red in Figure 3-4 and considering the Lee *et al.* 2021 to be one study although it is listed as if it were 2 studies in the figure), only 9 of the results reported from them showed a statistically significant value for the Beta value which indicates a decrease in IQ for each $\mu\text{g/dL}$ increase in blood lead (BPb). Note that in this list, non-significant results were also reported for some studies.

- Tatsuta *et al.* 2020 – in boys postnatal, with three non-significant results for prenatal in both boys and girls and girls postnatal
- Ruebner *et al.* 2019 – note that this is in children with chronic kidney disease
- Iglesias *et al.* 2020 – non-significant pre-site closure, significant post site closure
- Dantzer *et al.* 2020 – found toenail Pb not to be a reliable predictor of cognitive outcomes, but BPb was predictive
- Martin *et al.* 2021 – significant with high hair manganese (Mn), not significant with low hair Mn
- Hong *et al.* 2015 – other metal exposures considered as covariates
- Menezes-Filho *et al.* 2018 – Mn exposure considered as covariates
- Lucchini *et al.* 2012 – Mn exposure and interaction with Pb considered

These indicate that the heterogeneity is also seen within studies as well as across studies.

5. Of the more recent studies described in more detail in the remainder of Section 3.5.1.1, vital covariates were not included in the modeling done for some studies. Maternal or caregiver IQ was only considered as a covariate in three of the studies (Lee et al. 2021, Iglesias et al. 2020, and Dantzer et al. 2020) and although most of the rest did consider at least maternal education levels, three studies considered neither parental IQ nor education levels (Tatsuta et al. 2020, Martin et al. 2021, and Menezes-Filho et al. 2018). Only five of the studies (Taylor et al. 2017, Lee et al. 2021, Martin et al. 2021, Menezes-Filho et al. 2018 and Lucchini et al. 2012) considered interactions among the covariates and the Pb exposure variable (e.g. true confounding) with the Taylor et al. 2017 and Lee et al. 2021 identifying differences based on sex resulting in stratifying and the Martin et al. 2021 and Menezes-Filho et al. 2018 studies identifying interactions between the Pb and Mn levels in blood, hair or toenails which was not identified by Lucchini et al. 2012 although the interaction between Pb and Mn was considered in the model.

Yours sincerely,

Cynthia Van Landingham

Hi Cynthia,

Thanks for checking in on this. Yes, we will submit this conversation to the docket.

Best,
Evan

Evan, since our original e-mails concerning reproducing the results in Van Landingham et al. 2020 were put into the record (EPA-HQ-ORD-2020-0701-0005.pdf), will this conversation regarding the errata and you now being able to reproduce our results also be added?

Regard, Cynthia

Hi Cynthia,

Thank you for clarifying the discrepancy in the results. I can confirm that I was able to reproduce the results in Table S4 with the updated interaction coefficients. We would appreciate it if you could keep us up to date on the status of the errata.

As you previously noted, the draft ISA was already released (March 31st), but there is an opportunity to [provide input](#) to our advisory committee (the Clean Air Scientific Advisory Committee) via oral and/or written comments. Relevant comments to CASAC include identification of studies that were not included in the draft ISA.

Thanks again for taking the time to respond to our inquiry.

Best,
Evan

Subject: RE: Van Landingham et al. 2020

Ellen and Evan,

Sorry for the delay but it took me a while to track this down. As I think I told you in an earlier e-mail, the actual calculations were made using a feature in SAS that allows you to add records to your dataset used in the regression with no dependent variable value (in this case IQ) but with all the independent variables you want to use in the model (e.g. means for all the variables as specified in the paper or variations on those means). SAS does not use this record in the fitting process but does give a prediction for the dependent variable based on the model fit to the rest of the data and the values for lead and the covariates specified in the records added that have no observed value for the dependent variable. This is how I got the prediction for the IQ when varying the covariates, and also the values when varying the blood lead. To get the amount from a change of 1 in the lead, I subtracted the predicted values for lead of 1 from that for lead of 0 when all the covariates set at mean values.

The problem that you discovered came from the fact that I made an error in what is listed in Table 10 for the two values highlighted below.

Table 10. Model results for blood lead (BPb) and blood lead-associated variables – non-site specific.

Variable	Model 3 – linear model		Model 4 – log-linear Ln (BPb b-1) model	
	Variable value	Variable for interaction with BPb (confounder x BPb)	Variable value	Variable for interaction with BPb (confounder x ln(BPb b-1))
BPb	-0.1247		-4.945	
Mother's IQ	0.296	-0.0023587	0.383	-0.0003
Mother's education level	0.517	-0.0087	0.3967	-0.0051
HOME score	0.4745	0.0023	0.3789	0.0437

The value for the confounder x BPb listed for Mother's IQ and Mother's education level should be -0.00087 and -0.00704, respectively. This only effects this table, since I performed the operation as described above for the actual calculations in Tables 7,8,9,11 and 12 and the Supplemental Tables S4 and S5. I think that you will find that the values in Table S4 and Table 11 will be correct if you use these parameter values in the equations - with small differences that can happen considering rounding/truncation of the variable values or means reported in the paper versus the more complete values used inside the SAS process. This "error" does not affect our conclusions in the paper.

Sorry for any confusion that this caused and I will be sending an errata to the journal to correct this.

Cynthia

Subject: RE: Van Landingham et al. 2020

Dear Cynthia,

Thank you for your response to my request for clarification on your 2020 paper titled, "The effect of confounding variables in studies of lead exposure and IQ." I pasted your most recent email into the email chain from August 2022. Please note that I intended to copy Evan Coffman, the project lead for the Pb ISA, on the February 6, 2022 email but inadvertently left him off my response. He is copied now.

I reached out to Evan when I initially read your paper because I did not follow some of its underlying logic and conclusions. In his effort to better understand the paper he reproduced your site specific results in Table S5, but was not able to

reproduce the non-site specific results in Table S4 (select results also in Table 11).

To take the simplest example from Table S4, the paper states that "for 1 ug/dL BPb, the estimate for change in IQ is -0.203 for the linear model [...] when the confounders are set at an average". This result corresponds to the linear model results for the 1 ug/dL BPb column and the 0 row for each of the confounders. We used the following equation, average confounder values, and regression coefficients to reproduce the result, but got a different number:

Equation 1:

Change in IQ = BPb x (B1 + (B2 x maternal IQ) + (B3 x maternal education) + (B4 x HOME Score))

Non-site-specific average values (Table 5; bottom row):

Maternal IQ: 88.89

Maternal education: 11.12

HOME score: 34.49

Non-site-specific interaction coefficients (Table 10; Model 3):

BPb (B1): -0.1247

Maternal IQ intxn (B2): -0.0023587

Maternal education intxn (B3): -0.0087

HOME Score intxn (B4): 0.0023

Thus, holding all confounders fixed at 0, the change in IQ estimated for a BPb of 1 ug/dL =

BPb x (B1 + (B2 x maternal IQ) + (B3 x maternal education) + (B4 x HOME Score))

1 x (-0.1247 + (-0.0023587 x 88.89) + (-0.0087 x 11.12) + (0.0023 x 34.49))

(-0.1247 - 0.2097 - 0.0967 + 0.079327)

-0.35

The full set of results are pasted below. Please let us know if you can offer any clarification.

Best regards,

Ellen F. Kirrane (she/her/hers)

Senior Epidemiologist

U.S. EPA CPHEA

Ellen,

We communicated last year regarding the analyses in Van Landingham et al. 2020 and your ability to reproduce some of the values reported. I am checking back with you as to whether you completed your analysis. I have seen the draft ISA for lead and noted that our paper was not referenced in that document. Was it not included as you could not reproduce the results or was there some other reason that it was not included. If you are having problems reproducing, maybe I can help you with that. Let me know you would like to discuss this.

Regards, Cynthia

Sorry. I am semi retired. I will try to get back into my code next week to see if my answer below changes. All calculations were done in SAS using its ability to provide predictive values as part of the fitting process. Average value's were used for all variables either overall sires or specific to each site to get predictions with BPB values of 0 and 1. The difference provides the reported results.

Dear Dr. Van Landingham,

This is to follow up on the email of August 2 below seeking clarification on your paper. I am looping in Evan Coffman who is leading the Lead ISA team.

Best regards,

Ellen

Sorry, I am on vacation this week but will get back to you next week. But my memory says I calculated those as the difference of the predicted values.

Subject: Van Landingham et al. 2020

Dear Dr. Van Landingham,

I am writing to you as the corresponding author for the paper titled, "The effect of confounding variables in studies of lead exposure and IQ." Could you please explain how you calculated the estimated change in IQ for 1 microgram per dL BPb for both the linear and the loglinear models to obtain -0.203 and -2.36, respectively (Tables 11 and S4.) We are not able to obtain these results by using equation 1 and substituting the non site-specific results in table 10. I apologize if I missed something in the paper.

Best regards,

Date: Wednesday, May 31, 2023 10:06:37 AM
Attachments: [Corrected Table 10.docx](#)

Hello Josie,

Dr. Landingham would like to submit an erratum for the manuscript listed below published in CRT in 2020. The attached Word file has the corrected table.

In detail: Two values reported in Table 10 for Model 3 were reported incorrectly (linear model for the interaction variables for Mother's IQ and Mother's education level. Instead of the reported values of -0.0023587 and -0.0087, the values for the confounder × BPB listed for Mother's IQ and Mother's education level should be -0.00087 and -0.00704, respectively).

Cynthia Van Landingham , William G. Fuller & Rosalind A. Schoof (2020) The effect of confounding variables in studies of lead exposure and IQ, Critical Reviews in Toxicology,

50:9, 815-825, DOI: 10.1080/10408444.2020.1842851

Please let me know if you have any questions.

Best,
Jesse

Thanks Marissa.

Hi Jesse and Roger,

Could you please let know what the issue is as I couldn't follow the email trail properly.

All best,

Josie

Hello Josie,

Hope you are well!

I am forwarding the below author correction for their already-published article. Would you kindly be able to assist them with this issue?

Thank you and please let me know if you have further queries or concerns.

Best,

Marissa

Subject: RE: RE: Question

Marissa, Thanks for your instructions. The information you requested is below.

The mistake made was in two values reported in Table 10 for Model 3 – linear model for the interaction variables for Mother's IQ and Mother's education level. Instead of the reported values of -0.0023587 and -0.0087, the values for the confounder × BPB listed for Mother's IQ and Mother's education level should be -0.00087 and -0.00704, respectively. The attached Word file has the corrected table.

Hello All,

Thank you for your email!

I confirm any corrections to an already-published paper can be forwarded to the Production Team for handling.

Kindly reply to this email with the full article title, the corresponding author name and email address, and a file attachment with the corrected table. This information will be forwarded to the Production Team, who will make the necessary correction to your published article.

Please let me know if you have further queries or concerns.

Best,

Marissa

Subject:Re: RE: Question

Thanks for your reply. I have not heard from Marissa and I am not sure that I understand what you mean when you say it must be like submitting a new manuscript. Do I have to change the one table and submit the original manuscript as accepted or do I submit a letter to the editor detailing the errata (which is only 2 values listed in Table 10)? Could you be more specific about what is needed?

Thanks, Cynthia

Dear Cynthia and Roger,

I'm not exactly sure how to submit an errata, but my guess is that you can submit it through the ScholarOne system as if you were submitting a new manuscript. Hopefully, Marissa will be able to confirm.

Best,

Jesse

Subject: Re: Question

Cynthia;

It was great to hear from you although I wish it did not concern a problem. By copy of this e-mail I am asking two of my colleagues to assist you with advice on how to prepare a communication concerning an errata. Marissa is part of the T and F team. Jesse is now my assistant replacing my long time assistant, Mildred Morgan, who. passed away last April at age 92 years. She had along productive and enjoyable life. You probably had some contact with her over the more than a half century she worked with me.

If you ever have any questions related to Critical Reviews in Toxicology or my publications feel free to contact Jesse who works from her home in Colorado Springs.

I hope you will have another review paper to submit to Critical Reviews in Toxicology in the near future It is always a pleasure to publish papers you have authored or co-authored.

Best regards,

Roger

Hello Roger,

Long time sine we have talked. Unfortunately, I need to report an errata in my 2020 paper (citation below). The mistake was a transcription mistake in two values reported in Table 10 and does not affect any of the rest of the document including the supplemental tables.

Cynthia Van Landingham , William G. Fuller & Rosalind A. Schoof (2020) The

effect of confounding variables in studies of lead exposure and IQ, Critical Reviews in Toxicology,

50:9, 815-825, DOI: 10.1080/10408444.2020.1842851

I cannot seem to find the instructions on how to submit and errata to Critical Reviews in Toxicology. Can you help me?
